We retrospectively evaluated the diagnostic significance of carotid and vertebral sonography in predicting intracranial hypertension in 59 patients (3M:56 F = 28:31; mean age = 56 +/- 19) with various intracranial disorders, among them 21 with brain tumor and/or herniation. The intracranial pressure (ICP) was evaluated in all patients by at least two independent neurologic teams, based on the finding of severe focal neurologic deficits and/or a high ICP (> 25 mm Hg) without concurrent central nervous system (CNS) infection. Sonography was carried out in all cases by at least two different sonographers, blind to the ICP, and subsequently by a single well-experienced neuroradiologist, blinded to the sonographic findings, the findings of previous sonographies and the ICP. Routine radiologic studies were made in every case, including CT, conventional angiography (20), MR or both (5). Sonography revealed a wide range of vascular stenoses, occlusions, dilatations, and anomalous vascular structures. The carotid sonography showed the existence of extrinsic compression of the carotid bulb in 10 patients (17%), the carotid canal in 17 (29%), the carotid sheath in 16 (27%), and extrinsic compression of the internal carotid artery in 8 (13%). In 50% of the cases, an alteration of the lateral ventricles was observed, which was not correlated to the ICP. In 20% of the patients, sonography revealed additional vertebral stenoses (10), vertebral dilatations
